Brainstorm & Idea Prioritization Template:

During the brainstorming phase of the **Automated Network Request Management using ServiceNow** project, several ideas were evaluated to improve the efficiency of handling network-related requests such as VPN access, firewall changes, IP allocation, network troubleshooting, and Wi-Fi access. The primary objective was to automate the entire request lifecycle while minimizing manual intervention, reducing processing time, and improving service quality. Various potential features were identified, including a Service Catalog for standardized request submission, automated approval workflows, automatic assignment of requests to the appropriate network support team, SLA monitoring, email notifications, reporting dashboards, knowledge base integration, automatic ticket closure, AI-based request categorization, and chatbot support. These ideas were assessed based on business impact, implementation complexity, time-saving potential, scalability, user experience, and overall feasibility. High-priority features such as the Service Catalog, workflow automation, auto-assignment, SLA management, and notifications were selected because they provide significant operational benefits while being practical to implement within ServiceNow. Medium-priority features, including dashboards, reporting, knowledge base integration, and automatic ticket closure, were chosen to enhance visibility and user satisfaction. Advanced capabilities such as AI-driven request classification, predictive analytics, and chatbot integration were identified as future enhancements due to their higher implementation complexity. Based on this prioritization, the final solution automates the complete network request process from request submission and approval to task assignment, execution, notifications, and ticket closure. This approach is expected to significantly reduce manual effort, improve SLA compliance, enhance transparency, increase operational efficiency, and deliver a faster and more reliable experience for both end users and network administrators.
